# Project Report Group Panda

Java and C# in depth, Spring 2013

Christian Klauser Sander Schaffner Roger Walt

April 6, 2013

## 1 Introduction

This document describes the design and implementation of the  $Panda\ Virtual\ File\ System$  of group Panda. The project is part of the course  $Java\ and\ C\#\ in\ depth$  at ETH Zurich. The following sections describe each project phase, listing the requirements that were implemented and the design decisions taken. The last section describes a use case of using the  $Panda\ Virtual\ File\ System$ .

### 2 VFS Core

Give a short description (1-2 paragraphs) of what VFS Core is.

# 2.1 Requirements

Describe which requirements (and possibly bonus requirements) you have implemented in this part. Give a quick description (1-2 sentences) of each requirement. List the software elements (classes and or functions) that are mainly involved in implementing each requirement.

### 2.2 Design

Give an overview of the design of this part and describe in general terms how the implementation works. You can mention design patterns used, class diagrams, definition of custom file formats, network protocols, or anything else that helps understand the implementation.

#### 2.2.1 General Remarks

- Offsets & lengths in bytes.
- The VFS is organized in blocks with fixed BLOCK\_SIZE.
- All addresses are in number of blocks from 0 and of length 4 bytes.
- Only single links to blocks (not more than one hard-link) are allowed. This means that one file or directory can only be in one directory.
- Block address 0 is illegal, it means absence of a block.
- $B_S := BLOCK\_SIZE \& d-t := data-type$
- Offsets are absolute
- Strings are encoded in UTF-8

#### 2.2.2 Metadata

Metadata of the whole VFS starts at address 0.

Offset	Length	C# d-t	Description
0	4	UInt32	Number of blocks in entire VFS
4	4	UInt32	BLOCK_SIZE in bytes
8	4	UInt32	Address of root directory node
12	4	UInt32	Address of empty page block. Must
			never be 0
16	4	UInt32	break in number of blocks, see empty
			space management.
20	B_S -20	UInt32	Empty (initialized with 0)

Normal blocks are everywhere but at address 0.

### **Block Types**

- Directory blocks (many different blocks, with optional continuation blocks)
- File blocks (many different blocks, with optional continuation blocks)
- Data blocks (many different blocks)
- Empty space block (exactly one block, with optional continuation blocks)

#### Directory blocks

Contain file / directory names of current directory and their block addresses.

Offset	Length	C# d-t	Description
0	?	-	Arbitrary number of directory entries
B_S - 4	4	UInt32	Link to directory continuation block.
			0 here marks absence of continuation
			blocks.

Directory continuation blocks look the same as directory blocks and can link to other directory continuation blocks.

#### Directory entry

Offset	Length	C# d-t	Description
0	1	UInt8	If first bit (the least significant) set (==
			1), following address points to direc-
			tory. Else to file.
2	1	UInt8	Number of bytes in file name. 0 here
			marks end of directory block.
3	X	String	File / directory name
X	X + 4	UInt32	Address to file / directory block

#### File blocks

Contain addresses to data blocks.

Offset	Length	C# d-t	Description
0	8	UInt64	File size in bytes (to manage files
			smaller than block size)
8	?	UInt32	Arbitrary number of addresses to data
			blocks
B_S - 4	4	UInt32	Link to file continuation block. 0 here
			marks absence of continuation blocks.

File continuation blocks have file size 0 and can link to other file continuation blocks.

#### File blocks

Contain only plain binary data.

#### Empty space block

Contains addresses to empty blocks.

Offset	Length	C# d-t	Description
0	4	UInt32	Number of empty blocks in number of
			blocks
4	?	UInt32	Arbitrary number of addresses to
			empty blocks
BLOCK_	SEZE	UInt32	Link to empty space continuation
? 4			block. 0 here marks absence of contin-
			uation blocks.

#### 2.2.3 Empty space management

The VFS is designed to maintain an index of unused blocks. The addresses of the unused blocks are stored in the empty space block. Its address is stored in the VFS meta-data. This empty space block may also have empty space continuation blocks. But not every address to an empty block in the whole VFS can be stored in this empty space block. Instead, only addresses of empty blocks up to a maximum address, which is called break, is stored in this block. If there are no empty blocks left, the break must be increased by 1, and the new empty block addresses must be added to the empty space block. If the block next to break is freed, decrease the break, otherwise the address of this block to the empty space block or its last continuation block.

### 3 VFS Browser

#### [This section has to be completed by April 22nd.]

Give a short (1-2 paragraphs) description of what VFS Browser is.

### 3.1 Requirements

Describe which requirements (and possibly bonus requirements) you have implemented in this part. Give a quick description (1-2 sentences) of each requirement. List the software elements (classes and or functions) that are mainly involved in implementing each requirement.

### 3.2 Design

Give an overview of the design of this part and describe in general terms how the implementation works. You can mention design patterns used, class diagrams, definition of custom file formats, network protocols, or anything else that helps understand the implementation.

### 3.3 Integration

If you had to change the design or API of the previous part, describe the changes and the reasons for each change here.

# 4 Synchronization Server

### [This section has to be completed by May 13th.]

Give a short (1-2 paragraphs) description of what VFS Browser is.

# 4.1 Requirements

Describe which requirements (and possibly bonus requirements) you have implemented in this part. Give a quick description (1-2 sentences) of each requirement. List the software elements (classes and or functions) that are mainly involved in implementing each requirement.

# 4.2 Design

Give an overview of the design of this part and describe in general terms how the implementation works. You can mention design patterns used, class diagrams, definition of custom file formats, network protocols, or anything else that helps understand the implementation.

### 4.3 Integration

If you had to change the design or API of the previous part, describe the changes and the reasons for each change here.

# 5 Quick Start Guide

### [optional: This part has to be completed by April 8th.]

If you have a command line interface for your VFS, describe here the commands available (e.g. ls, copy, import).

#### [This part has to be completed by May 13th.]

Describe how to realize the following use case with your system. Describe the steps involved and how to perform each action (e.g. command line executions and arguments, menu entries, keyboard shortcuts, screenshots). The use case is the following:

- 1. Start synchronization server on localhost.
- 2. Create account on synchronization server.
- 3. Create two VFS disks (on the same machine) and link them to the new account.
- 4. Import a directory (recursively) from the host file system into Disk 1.
- 5. Dispose Disk 1 after the synchronization finished.
- 6. Export the directory (recursively) from Disk 2 into the host file system.
- 7. Stop synchronization server.
